Abstract

This paper gives a method that maps the static magnetic field due to a system of parallel current-carrying wires to a complex function. Using this function simplifies the calculation of the magnetic field energy density and inductance per length in the wires, and we reproduce well-known results for this case.

Keywords

Magnetostatics, Inductance, Magnetic Field

1. Introduction

This paper points out a convenient way to calculate the magnetic field due to parallel, current-carrying wires. Defining a coordinate system such that the wires run along the z -direction, the magnetic field due to a current-carrying wire will be in the x - y -plane. We construct a complex function, $f(x+iy)$, from the components of the magnetic field: $f = B_x - iB_y$. The magnetic field due to a constant set of currents is determined from Ampere's law, which we will show is equivalent to the statement that

$$\int_c f(\xi) d\xi = \mu_0 I_{enc}, \quad (1)$$

where $\xi = x+iy$, I_{enc} is the sum of currents enclosed by the contour c in the x - y -plane, and μ_0 is the permeability of free space. We show that the form for the function f that reproduces the known magnetic field from a constant current i in a single wire at the position (x_0, y_0) is

$$f(\xi) = \frac{\mu_0 I}{2\pi i (\xi - \xi_0)}, \quad (2)$$

where $\xi_0 = x_0 + iy_0$. The principle of superposition holds for Ampere's law, so if there are many current-carrying wires, the magnetic field is the sum of magnetic

fields from each wire.

These ideas are based on constant currents. In this magnetostatic case, inductance can be simply calculated. Once inductance is calculated, then it can be used to determine circuit behavior in the case when there are slowly varying currents. To be precise, in this paper, we will define inductance as relating currents to total energy stored in a magnetic field according to:

$$U = \frac{1}{2} \sum_{j,k} L_{jk} I_j I_k. \tag{3}$$

L_{jk} is the inductance matrix (including self-inductance and mutual inductance), U is the total energy stored in the magnetic field, and I_k is the current carried in wire- k . We find the self-inductance per length of a wire is

$$\frac{L_{nn}}{l} = \frac{\mu_0}{4\pi^2} 2\pi \int_a^\Lambda \frac{1}{r^2} r dr = \frac{\mu_0}{2\pi} \ln\left(\frac{\Lambda}{a}\right). \tag{4}$$

Λ and a are long and short distance cut-offs respectively. The mutual inductance per length of two wires is

$$\frac{L_{nj}}{l} = \frac{\mu_0}{2\pi} \ln\left(\frac{\Lambda}{r_{nj}}\right), \tag{5}$$

where r_{nj} is the distance from wire n to wire j . These are standard results [1] [2]. Measurements and calculations of the self-inductance of actual thin wires of length l and radius ρ are consistent with (4) with $\Lambda = 2l/e$ and $a = \rho$. The measured mutual inductance of two thin wires separated by a distance d is also consistent with (5) with $\Lambda = 2l/\exp(-1 + d/l)$ [3].

We would like to mention that there are similar techniques using stream functions in fluids to understand vortices [4], and also some magnetic field problems in the absence of currents [5].

2. Relation between Ampere’s Law and a Contour Integral

Ampere’s law in SI units in integral form is

$$\oint_c \mathbf{B} \cdot d\mathbf{r} = \mu_0 I_{enc}, \tag{6}$$

where I_{enc} is the current puncturing the area enclosed by path c , with the sign of the current given by the right hand rule.

If the path c is in the x - y plane, Ampere’s law formally looks like

$$\oint_c (B_x dx + B_y dy) = \mu_0 I, \tag{7}$$

with positive currents I moving in the positive z -direction.

Consider a complex function $f(\xi)$, with $\xi = x + iy$, such that $f(\xi) = B_x - iB_y$. Then substituting f into the contour integral $\int_c f(\xi) d\xi$, where the contour c in the complex plane is identical to the path of the line integral in (7) (meaning the same x - and y -values are traversed in the line integral as in the complex contour integral), yields

$$\int_c f(\xi) d\xi = \oint_c (B_x dx + B_y dy) + i \oint_c (B_x dy - B_y dx). \tag{8}$$

Therefore,

$$\oint_c \mathbf{B} \cdot d\mathbf{r} = \text{Re} \left\{ \int_c f(\xi) d\xi \right\} = \mu_0 I_{enc}.$$

The imaginary part of the complex integral (8) is

$$\oint_c (B_x dy - B_y dx).$$

This can be written in terms of a parameter t that parameterizes the contour as

$$\int_{t_1}^{t_2} \left(B_x \frac{dy}{dt} - B_y \frac{dx}{dt} \right) dt. \quad (9)$$

The integrand is formally $B_x v_y - B_y v_x = -(\mathbf{v} \times \mathbf{B})_z$. This integrand is proportional to the z -component of the Lorentz force, $\mathbf{F} = q\mathbf{v} \times \mathbf{B}$, on a charge q . If we return to the original complex integral (8), the integral will remain the same on any change of the contour c so long as the enclosed singularities (places where f is not analytic) remain the same. In particular if the only singularities are isolated poles in f and if we consider the contours c_k as being an infinitesimal circle surrounding a pole at $\xi_k = x_k + iy_k$ (in the same direction, clockwise or counterclockwise as the contour c), then the complex integral (8) can be written as [6]

$$\int_c f(\xi) d\xi = \sum_k \int_{c_k} f(\xi) d\xi.$$

Clearly the real and imaginary parts of contour integral can then be written in the same way, in particular

$$\oint_c (B_x dy - B_y dx) = \sum_k \oint_{c_k} (B_x dy - B_y dx), \quad (10)$$

where c_k is now interpreted as an infinitesimal circle around a current-carrying wire (the current being the place where the magnetic field becomes non-analytic) positioned at (x_k, y_k) .

Each of the integrals in the sum in (10) can be parameterized and written in the form of (9). We can imagine each of these integrals is then proportional to the time integral of the z -component of the force on a test charge moving around an infinitesimal circle surrounding the current-carrying wire. For a single wire, the magnetic field is either parallel or antiparallel to the circle surrounding the wire, and hence the Lorentz force is zero. In the case of multiple wires, however, this is not the case. Consider two wires, which we can denote as wire-1 and wire-2. Consider a small circle around wire-1, c_1 . Let \mathbf{B}_1 be the magnetic field due to the current in wire-1 and \mathbf{B}_2 be the magnetic field due to the current in wire-2. The magnetic field along the path c_1 can be written as $\mathbf{B} = \mathbf{B}_1 + \mathbf{B}_2$. Lets consider the integral

$$\oint d\mathbf{r} \times \mathbf{B} = \int_{t_1}^{t_2} \mathbf{v} \times \mathbf{B} dt,$$

where t parameterizes the circular path c_1 , with t_2 and t_1 being the value of the parameter t at the beginning and end of one circle around the wire, and $\mathbf{v} = \frac{d\mathbf{r}}{dt}$.

This integral can then be written as

$$\int_{t_1}^{t_2} \mathbf{v} \times \mathbf{B} dt = \int_{t_1}^{t_2} \mathbf{v} \times \mathbf{B}_1 dt + \int_{t_1}^{t_2} \mathbf{v} \times \mathbf{B}_2 dt$$

The first integral on the right hand side of the above equation is zero, by the argument presented for the single wire. Let us consider the second integral on the right hand side of the above equation. If c_1 has a radius which is very small compared to the distance from wire-1 to wire-2, then B_2 is approximately uniform over the circle c_1 . Hence the integral is approximately

$$\int_{t_1}^{t_2} \mathbf{v} \times \mathbf{B}_2 dt \approx \left(\int_{t_1}^{t_2} \mathbf{v} dt \right) \times \mathbf{B}_2 = \left(\oint_{c_1} d\mathbf{r} \right) \times \mathbf{B}_2 = 0,$$

since the integral of $d\mathbf{r}$ is zero over a closed path. A similar argument can be made in the case of many wires. Therefore in the case of a magnetic field due to multiple wires

$$\oint_{c_i} d\mathbf{r} \times \mathbf{B} = 0, \tag{11}$$

and this means that in (10),

$$\oint_{c_k} (B_x dy - B_y dx) = 0. \tag{12}$$

This means that the imaginary part of the complex integral (8) should vanish.

We should note that there is an important condition for (12) to hold. We needed to have the radius of the circles around each of the wires be much smaller than the distance between the wires, so the magnetic field due to one wire could be considered uniform at a different wire. If a is the radius of a wire and d is the shortest distance between wires, then the condition for our theory to hold is that

$$a \ll d. \tag{13}$$

We are left with

$$\int_c f(\xi) d\xi = \oint_c \mathbf{B} \cdot d\mathbf{r} = \mu_0 I \tag{14}$$

as our condition on f to be $B_x - iB_y$. This proves (1).

The residue theorem for contour integrals is [6]

$$\int_c f(\xi) d\xi = 2\pi i R, \tag{15}$$

where R is the sum of the residues of f enclosed in c . The formula for the residue of a function $f(\xi)$ at a pole of order n at $\xi = a$ is

$$R[f(a)] = \frac{1}{(n-1)!} \left\{ \frac{d^{n-1}}{d\xi^{n-1}} \left[(\xi - a)^n f(\xi) \right] \right\}_{\xi=a} \tag{16}$$

For (14) to hold, we must have

$$2\pi i R = \mu_0 I. \tag{17}$$

A simple form of f which satisfies (14) and (17) for a wire carrying current I in the z -direction at (x_0, y_0) is

$$f(\xi) = \frac{\mu_0 I}{2\pi i (\xi - \xi_0)}, \tag{18}$$

where $\xi_0 = x_0 + iy_0$. Taking the real and imaginary parts of $f(\xi)$, and com-

paring with $f = B_x - iB_y$, we find

$$\begin{aligned} B_x &= -\frac{\mu_0 I}{2\pi r} \frac{y - y_0}{r}, \\ B_y &= \frac{\mu_0 I}{2\pi r} \frac{x - x_0}{r}, \end{aligned} \quad (19)$$

where $r^2 = (x - x_0)^2 + (y - y_0)^2$.

We note that in cylindrical coordinates, $\hat{\phi} = -\sin\phi\hat{x} + \cos\phi\hat{y}$, where $\sin\phi = \frac{y - y_0}{r}$ and $\cos\phi = \frac{x - x_0}{r}$. We see that (19) is precisely the field

$\mathbf{B} = \frac{\mu_0 I}{2\pi r} \hat{\phi}$ that one expects according to Ampere's law.

The reader can easily see that (18) is not unique in yielding an integral whose residue obeys (17). In fact adding any analytic function to (18) will give an identical result and the condition $\nabla \cdot \mathbf{B} = 0$ will hold as well. Also, there is the possibility of higher order-poles with the same residue. For the purpose of this paper, we will choose (18) because it yields the expected field for a single wire. We would also like to note that a second order pole gives a 2-dimensional dipole field for the magnetic field. Now, it is straightforward to generalize (18) to any number of wires carrying current in the z -direction, at the positions (x_j, y_j) . We simply write

$$f(\xi) = \frac{\mu_0}{2\pi i} \sum_j \frac{I_j}{\xi - \xi_j}, \quad (20)$$

and then take the real and imaginary parts of this to find the x and y components of the magnetic field.

3. Energy Density and Inductance

Energy density in a magnetic field is $u_B = \frac{1}{2\mu_0} B^2$. So for the magnetic field in the x - and y -directions, we can write $u_B = \frac{1}{2\mu_0} f^* f$. The total energy stored in the magnetic field is then

$$U = \frac{1}{2\mu_0} \int f^* f d^3\mathbf{r}, \quad (21)$$

where the integral is over all space. The total energy stored in a magnetic field that is created by a system of currents I_j is related to the inductances according to

$$U = \frac{1}{2} \sum_{j,k} L_{jk} I_j I_k \quad (22)$$

where I_j is the current in wire j . L_{jk} is the mutual inductance of wires j and k and is symmetric in its indices. L_{kk} is the self inductance of wire k .

Suppose we add a current I_n to the system of currents in the z -direction. Let U_0 be the energy stored in the magnetic field in the absence of current I_n and let U be the energy stored in the magnetic field in the presence of I_n . We can

then write

$$\frac{U - U_0}{I_n} = \frac{1}{2} \sum_{j \neq n} [L_{nj} I_j + L_{jn} I_j] + \frac{1}{2} L_{nn} I_n = \sum_{j \neq n} L_{nj} I_j + \frac{1}{2} L_{nn} I_n \tag{23}$$

Let f_0 be the function $f(\xi)$ in the absence of I_n and let f be the function $f(\xi)$ in the presence of I_n . Then

$$U - U_0 = \frac{1}{2\mu_0} \int [|f|^2 - |f_0|^2] d^3r \tag{24}$$

and

$$f = f_0 + \frac{\mu_0 I_n}{2\pi i (\xi - \xi_n)} \tag{25}$$

Plugging (25) into (24), then dividing by I_n , we find that

$$\frac{U - U_0}{I_n} = \frac{1}{4\pi i} \int \left[\frac{f_0^*}{\xi - \xi_n} - \frac{f_0}{\xi^* - \xi_n^*} + \frac{i I_n}{2\pi |\xi - \xi_n|^2} \right] d^3r \tag{26}$$

Plugging in the definition of f from (20), we find that

$$\begin{aligned} \frac{U - U_0}{I_n} &= \sum_{j \neq n} I_j \frac{\mu_0}{8\pi^2} \int \left[\frac{1}{(\xi - \xi_j)(\xi^* - \xi_n^*)} + c.c. \right] d^3r \\ &+ I_n \frac{\mu_0}{8\pi^2} \int \frac{1}{(\xi - \xi_n)(\xi^* - \xi_n^*)} d^3r. \end{aligned} \tag{27}$$

Comparing (27) with (23), we arrive at a formulae for both the self inductance and the mutual inductance. The self inductance is

$$L_{nn} = \frac{\mu_0}{4\pi^2} \int \frac{1}{(\xi - \xi_n)(\xi^* - \xi_n^*)} d^3r = \frac{\mu_0 l}{4\pi^2} \int \frac{1}{(\xi - \xi_n)(\xi^* - \xi_n^*)} dx dy, \tag{28}$$

and the mutual inductance is

$$\begin{aligned} L_{nj} &= \frac{\mu_0}{8\pi^2} \int \left[\frac{1}{(\xi - \xi_j)(\xi^* - \xi_n^*)} + \frac{1}{(\xi^* - \xi_j^*)(\xi - \xi_n)} \right] d^3r \\ &= \frac{l\mu_0}{8\pi^2} \int \left[\frac{1}{(\xi - \xi_j)(\xi^* - \xi_n^*)} + \frac{1}{(\xi^* - \xi_j^*)(\xi - \xi_n)} \right] dx dy, \end{aligned} \tag{29}$$

where l is the length of the wires.

The self-inductance, Equation (28), can be directly integrated. We note that $(\xi - \xi_n)(\xi^* - \xi_n^*) = (x - x_n)^2 + (y - y_n)^2 = r^2$. Where we set the origin of the coordinate system to the position of wire n and then convert to polar coordinates. Performing the integration in polar coordinates, we arrive at the inductance per length of the wire being

$$\frac{L_{nn}}{l} = \frac{\mu_0}{4\pi^2} 2\pi \int_a^\Lambda \frac{1}{r^2} r dr = \frac{\mu_0}{2\pi} \ln \left(\frac{\Lambda}{a} \right). \tag{30}$$

Here we introduced long range and short range cutoffs for the integration, Λ and a respectively, and the self-inductance is only written to logarithmic accuracy, as per usual [1]. $\Lambda = 2l/e$ and $a = \rho$, where ρ is the radius of the wire, gives

good agreement with experiment in the case of long, thin wires [3].

The integral for the mutual inductance can also be done, but is a little more involved. Here again, we find it helpful to set the origin of the x - y coordinate system to the position of wire n , and then convert to polar coordinates. Let $\zeta = re^{i\theta}$ and $\zeta_j = r_j e^{i\phi}$. Then the integral (29) becomes

$$\frac{L_{nj}}{l} = \frac{\mu_0}{8\pi^2} \int_0^\infty dr \int_0^{2\pi} d\theta \left[\frac{1}{r - r_j e^{-i(\phi-\theta)}} + \frac{1}{r - r_j e^{i(\phi-\theta)}} \right]. \quad (31)$$

We first perform the integral over θ . We do this via residues [6]. In the first integral on the right hand side of (31), write $u = e^{-i\theta}$, and then $d\theta = \frac{du}{-iu}$, and the integral becomes a contour integral over a unit circle in the complex- u plane, traversed in the clockwise direction, call this contour- c . In the second integral on the right hand side, we write $u = e^{i\theta}$, so $d\theta = \frac{du}{iu}$, and the integral becomes the integral over a unit circle in the complex- u plane, traversed in the counterclockwise direction. We'll call this contour c . Performing these contour integrals, we find that the integral over θ in (31) is

$$\int_0^{2\pi} d\theta \left[\frac{1}{r - r_j e^{-i(\phi-\theta)}} + \frac{1}{r - r_j e^{i(\phi-\theta)}} \right] = \begin{cases} \frac{4\pi}{r} & r > r_j \\ 0 & r < r_j \end{cases} \quad (32)$$

In place of r_j , for generalization purpose, we introduce the distance r_{nj} which is the distance between wires n and j . The mutual inductance per length is given by

$$\frac{L_{nj}}{l} = \frac{\mu_0}{2\pi} \int_{r_{nj}}^\Lambda \frac{dr}{r} = \frac{\mu_0}{2\pi} \ln \left(\frac{\Lambda}{r_{nj}} \right), \quad (33)$$

where we introduced a long range cutoff Λ for the integral over r . Again this is written only to logarithmic accuracy. In the case of two parallel wires separated by a distance d , $\Lambda = 2l/\exp(-1+d/l)$ gives good agreement with experiment [3].

4. Conclusion

We note that these results for inductance are well known, but illustrate our method. In a future paper, we hope to apply this formalism to the calculation of inductance in different systems. We would also like to mention that the similarity between our formalism and the velocity stream function in fluid flow, with currents being replaced by vorticity [4] leads naturally to a nice qualitative picture of the magnetic field around arrays of wires, or around arrays of currents. In the future, we would to examine the interplay between the energy density of currents in a solid and the force between parallel current carrying wires. It is our belief that the magnetic field may break into an array of vortices similar in structure to the currents around magnetic flux lines in type II superconductors, depending on the solid [7] [8].
